# Newton's Second Law

*Force equals mass times acceleration.*

$$F = ma$$

Acceleration: a measurement of how quickly an object is changing speed.

# Acceleration

- ▶ An *unbalanced force* causes something to accelerate.
  - ▶ A force can cause motion only if it is met with an *unbalanced force*.
  - ▶ Forces can be balanced or unbalanced.
  - ▶ Depends on the **net force** acting on the object
  - ▶ **Net force ( $F_{\text{net}}$ ):** The sum total and direction of all forces acting on the object.
- ▶ **Net forces: Always cause acceleration.**

# Balanced Versus Unbalanced

$$\begin{array}{c} \text{→} + \text{←} = 0 \\ \text{Net Force} = 0 \end{array}$$

Balanced forces cause no acceleration.

# Balanced Versus Unbalanced

$$\begin{array}{c} \rightarrow + \leftarrow = \rightarrow \\ \text{Net Force} = \rightarrow \end{array}$$

$$\begin{array}{c} \rightarrow + \rightarrow = \rightarrow \\ \text{Net Force} = \rightarrow \end{array}$$

Unbalanced forces  
cause acceleration.

# What does $F = ma$ mean?

Force is *directly proportional* to mass and acceleration. Imagine a ball of a certain mass moving at a certain acceleration. This ball has a certain force.

Now imagine we make the ball twice as big (double the mass) but keep the acceleration constant.  $F = ma$  says that this new ball has *twice the force* of the old ball.

Now imagine the original ball moving at twice the original acceleration.  $F = ma$  says that the ball will again have *twice the force* of the ball at the original acceleration.

In Other Words...

Small Force = Small Acceleration

In Other Words...

Large Force = Large Acceleration

$F$  →

$a$

So....if you push twice as hard, it accelerates twice as much.

# But there is a twist....

- Acceleration is **INVERSELY** related to the mass of the object.
- 

In other words.....using the same amount of force....

# What does $F = ma$ say?

$F = ma$  basically means that the force of an object comes from its mass and its acceleration.

Force is measured in

Newtons (N) = mass (kg) x acceleration ( $\text{m/s}^2$ )

Or

$\text{kg m/s}^2$

$$1 \text{ Newton} = 1 \text{ kg} \cdot \frac{\text{m}}{\text{s}^2}$$

# High Mass

Something very massive (high mass) that's changing speed very slowly (low acceleration), like a glacier, can still have great force.

# Low Mass

Something very small (low mass) that's changing speed very quickly (high acceleration), like a bullet, can still have a great force. Something very small changing speed very slowly will have a very weak force.

# In Summary

- ▶ The acceleration of an object is directly proportional to the net force & inversely proportional to its mass.
- ▶  $F = ma$
- ▶ Force = Mass x Acceleration

*Newton*

# How Does Weight Tie In?

- **Mass** is the quantity of matter in an object. More specifically, mass is a measure of the inertia, or “laziness,” that an object exhibits in response to any effort made to start it, stop it, or otherwise change its state of motion.
- **Weight** is the force of gravity on an object.
- If force is equal to mass x acceleration then, Weight is equal to mass x acceleration due to gravity

# Weight

- So on earth, your weight is
  - Your Mass  $\times$  9.8 m/s/s
- When you are drawing FBDs and the force of gravity factors in (almost always), you can figure out the value of that force
- For example, if I say a 2kg book is resting on a table...
  - The force due to gravity (weight) is  $2 \times 9.8$
  - The normal force would be the same but opposite direction
